Introduction

However, the manner of Internet usage essentially changed during the first decade of 21st century. Using the Internet and using the web browser became almost synonyms. People use the web browser as the primary platform to do every single task on the Internet. Sometimes it's not even possible to use the other internet services without visiting certain web page in the web browser and performing the authentication there.¹ Considering the mentioned fact, web browsers became also the basic platform for the communication tools. Even though the purpose of the world wide web and HTTP protocol was completely different at first (displaying single documents connected via hypertext links), it appeared that there is the need of common rich applications running withing web browser - rich internet application. So popular social networks are built on top of the web browser platform and they are used by more than billion people over the world. [5] And the main reason why the social networks are so popular is the real-time stream of news and messages from the other people. By the beginning of the year 2013, I would say that static web is dead - users prefer interactivity.

As mentioned above, the web browser became one of the most popular platforms. Celebrio, simple software for the elderly simulating the operating system interface, is typical

1

example of rich internet application. [3] All the topics mentioned in the previous paragraph appeared to be very important in the system. When interviewing the elderly people in the Czech Republic, it appeared that almost 90 % of the elderly computer users use the real-time communication (RTC) applications, mostly Skype. [4] Interaction with their loved ones is the most desired benefit they expect from the computer. Therefore, creating real-time application, text messenger supporting video calling, became not only programming challenge but also a business goal.

Considering the fact the people like real-time communication while using web browser brings us the question what the currently available solutions are. There are “big players” providing their own services as closed-source, without the possibility to use them. To name the most important, it’s Google Talk web browser client and Facebook chat, using XMPP protocol. [8][6] Even though Facebook chat service is not pure XMPP server implementation (the message and presence engine is proprietary system of Facebook implemented mostly in C++ and Erlang), they provide the possibility to connect to the “world of Facebook Chat” via XMPP as proxy. [7] Combination of the facts that XMPP is open technology with open-sourced client and server implementations [13] and the big internet companies also use it persuaded us to use it in our communication application too. XMPP itself and its usage in web applications is described in **Chapter 3, “Extensible Messaging and Presence Protocol”**.

Since the web browser was designed to perform simple requests/response interaction, it is not a typical platform for building real-time application. Thus, there is a need for an extra layer enhancing or even completely replacing the common way HTTP communicates. Within the scope of this thesis, namely the WebSockets and HTTP long polling approaches are used. The two of them and basic information about several others are covered in **Chapter 2, “Bidirectional communication”**.

There are many existing real-time chat-based applications over the Internet we could have used. However, none of them suited our needs perfectly. Celebrio has very specific graphical user interface (GUI) and there is a need to integrate both text-based chat and video calling. Just to mention, there is commercial chat module Cometchat² or even open project Jappix.³ Video calling web browser applications are provided for example by Tok-Box Inc.⁴ Nevertheless, following the rule that “If you have to customize 1/5 of a reusable component, it’s likely better to write it from scratch”, [2] just very generic existing libraries (Strophe.js) and APIs (OpenTok) were used for implementing brand new application called *Celebrio Talker*. The general approaches when building web browser based chat application are mentioned in **Chapter 4, “XMPP client in Javascript”**. Within the programming part of the thesis, the real-time text chat application, video calling application and simple “inter-process” communication tool for Celebrio has been implemented. Celebrio Talker application itself, its architecture and the specific procedures used to create it are described in **Chapter 5, “Talker”**.

2. <http://www.cometchat.com/>

3. <https://project.jappix.com/>

4. <http://www.tokbox.com/>

It has been said that Skype⁵ is the most favorite communication tool among the target audience. If it had been implemented, the existing customer base could be used and converted to our messaging application. However, there is one big pitfall in this approach. Skype license strictly prohibits incorporating their software into mobile devices. [12] They support only prompting the official Skype client to be opened via Skype URI, which is insufficient for Celebrio since the messaging client has to be built in the system, with the corresponding user interface.

Finally, there are several notes about “inter-process communication” between different applications running separately in various browser frames, tabs or even windows. **Chapter 6, “Inter-process Communication Framework”** covers this topic and describes the issues we came accross when implementing such functionality for Celebrio, where every application runs in separate iframe.

5. <http://www.skype.com/>

Chapter 2

Bidirectional communication

The very essence of every instant messaging is the bidirectional stream where both sides can immediately *push* new data and the other side (or more other sides, respectively) is promptly notified without the need to perform any manual *pull* (update) action.¹ Such use case requires appropriate transport layer on top which the application can send the messages via any other protocol. When using HTTP, there is a TCP connection opened by the client (web browser) through which the data is sent. However, according to the HTTP protocol, the communication is strictly initiated by the client - HTTP is a request/response protocol. [10] So, when one needs the web browser application to communicate in both directions, HTTP protocol must be hacked somehow or another communication channel has to be used. This chapter covers both.

2.1 Using HTTP requests

Historically the first approach, for a very long time the only one, is hacking HTTP to achieve RTC. The idea is very simple, depicted in TODO figure. Generally, the client sends an extra request and it is not awaiting the response immediately. Instead, the server keeps the request for some time

The other way how to successfully implement XMPP communication between web browser and the client (and of course, communication between two clients, since it is always mediated by certain server) is emulating the connection with mechanisms overallly called *Comet*.

2.2 WebSockets

Unless HTML5 technology called *WebSockets* is used, neither the client nor the server can establish permanent TCP connection. Usually if the WebSockets are used, the XMPP server needs one extra layer, usually implemented as the server plugin, to be able to communicate directly with the web browser. This approach is covered in [Section 3.3](#).

1. In this thesis, this behaviour is commonly referred as RTC. The “real-time part” relates mostly to the server part since the application running in the web browser can perform the AJAX request on background anytime and the server receives the request instantly. Before AJAX became the essential part of every web app, ifram

2.3 Existing RTC frameworks

Actually, there are other options such as using various browser plugins (e.g. Adobe Flash) to provide the base layer for TCP connections, but such tools has not been used within this thesis and are not further dealt with.

Describe other approaches to RTC in WB than XMPP. Tell why we didn't use them (or that we used - OpenTok).

Mention:

OpenTok

SignalR (.NET)

WebRTC (<http://www.webrtc.org/>)

Google hangouts API

Chapter 3

Extensible Messaging and Presence Protocol

Extensible Messaging and Presence Protocol (XMPP) technologies were invented by Jeremie Miller in 1998. [14] It is one of the most widespread technologies for instant messaging (IM),¹ i.e. exchanging the text or multimedia data between several endpoints. The “native” implementation of XMPP works right on top of TCP protocol: XMPP endpoint (called client as it represents the first actor in client-server architecture) opens long-lived TCP connection. Then, both the client and the server negotiate and open XML streams so there is one stream in each direction. [14] When the connection is established, both client and server can push any changes as XML elements to the stream and the other side obtains them immediately. Usual XMPP clients are standalone applications able to open TCP connection and listen to the stream opened by the server.

3.1 Fundamental building blocks in XMPP

Mention the terms as stanza, roster, describe the subscription mechanism.

3.2 XMPP over BOSH

Describe BOSH (<http://xmpp.org/extensions/xep-0124.html>)

and XMPP Over BOSH (<http://xmpp.org/extensions/xep-0206.html>).

Later on, description of BOSH extension, including the advantages and limitations. Describe also the connection to HTTP protocol.

3.3 XMPP over WebSockets

luajit - lua jit compiler

It was necessary to install: `apt balíky luajit + liblua5.1-bitop0`

TODO create diagram here (XMPP server - plugin - incoming connection vs xmpp server - standard connection).

1. Acutally, the IM client or even the technology itself is sometimes called “Instant Messenger”. This term is registered as a trademark by AOL company. [1]

3.4 Jingle

Jingle extension - multimedia.

<http://xmpp.org/extensions/xep-0166.html>

3.5 Inter-process communication

Pub-sub extensions for inter-process communication.

<http://xmpp.org/extensions/xep-0060.html>

Chapter 4

XMPP client in Javascript

Describe the tools that can be used to implement RTC in WB (and which were used to implement Celebrio Talker)

- Strophe (simple XMPP in Javascript)

- Strophe connecting/attaching - security issues. TODO programming

- Strophe plugins

- Possible server-side implementations (JAXL, XMPPHP, ...)

Chapter 5

Talker

Describe the Talker application in Celebrio.

Mention what we expected from the app (value proposition)

Then, application analysis, design and implementation.

Describe the architecture and used tools&frameworks: JS + Ember.js, OpenTok, WebSockets in new OpenTok

Don't forget to use UML: use case diagram, class diagram (if any), sequence/action diagram

5.1 Ember.js

Describe Javascript client-side MVC frameworks overall, compare, tell why we used Ember

5.1.1 Subsection about Ember...

Chapter 6

Inter-process Communication Framework

Implement and describe framework for inter-process communication in Celebrio.

First, the lightweight one (which we already have), then implement the "heavy" one, if there's enough time.

Chapter 7

Conclusion

conclusion

7.1 Another part of the conclusion

Another part of the conclusion... just to have subchapter here
